

①

DMD

$$\underline{X}' = \underline{X}(t + \Delta t) = \hat{A} \underline{X}(t) \quad \hat{A} \equiv \text{Koopman Operator}$$

$$\frac{dx}{dt} = \hat{A}x \quad \text{and} \quad \hat{A}x \Rightarrow Ax = \lambda x$$

$$\frac{dx}{dt} = \lambda x \quad \boxed{x(t) = c_1 e^{+\lambda \Delta t}}$$

$$\frac{dx}{x} = \lambda dt$$

so DMD solve  $\underline{A} \underline{\Phi} = \underline{\Phi} \underline{\Lambda}$   
 $\underline{\Phi} \equiv \text{Dynamic eigen modes}$

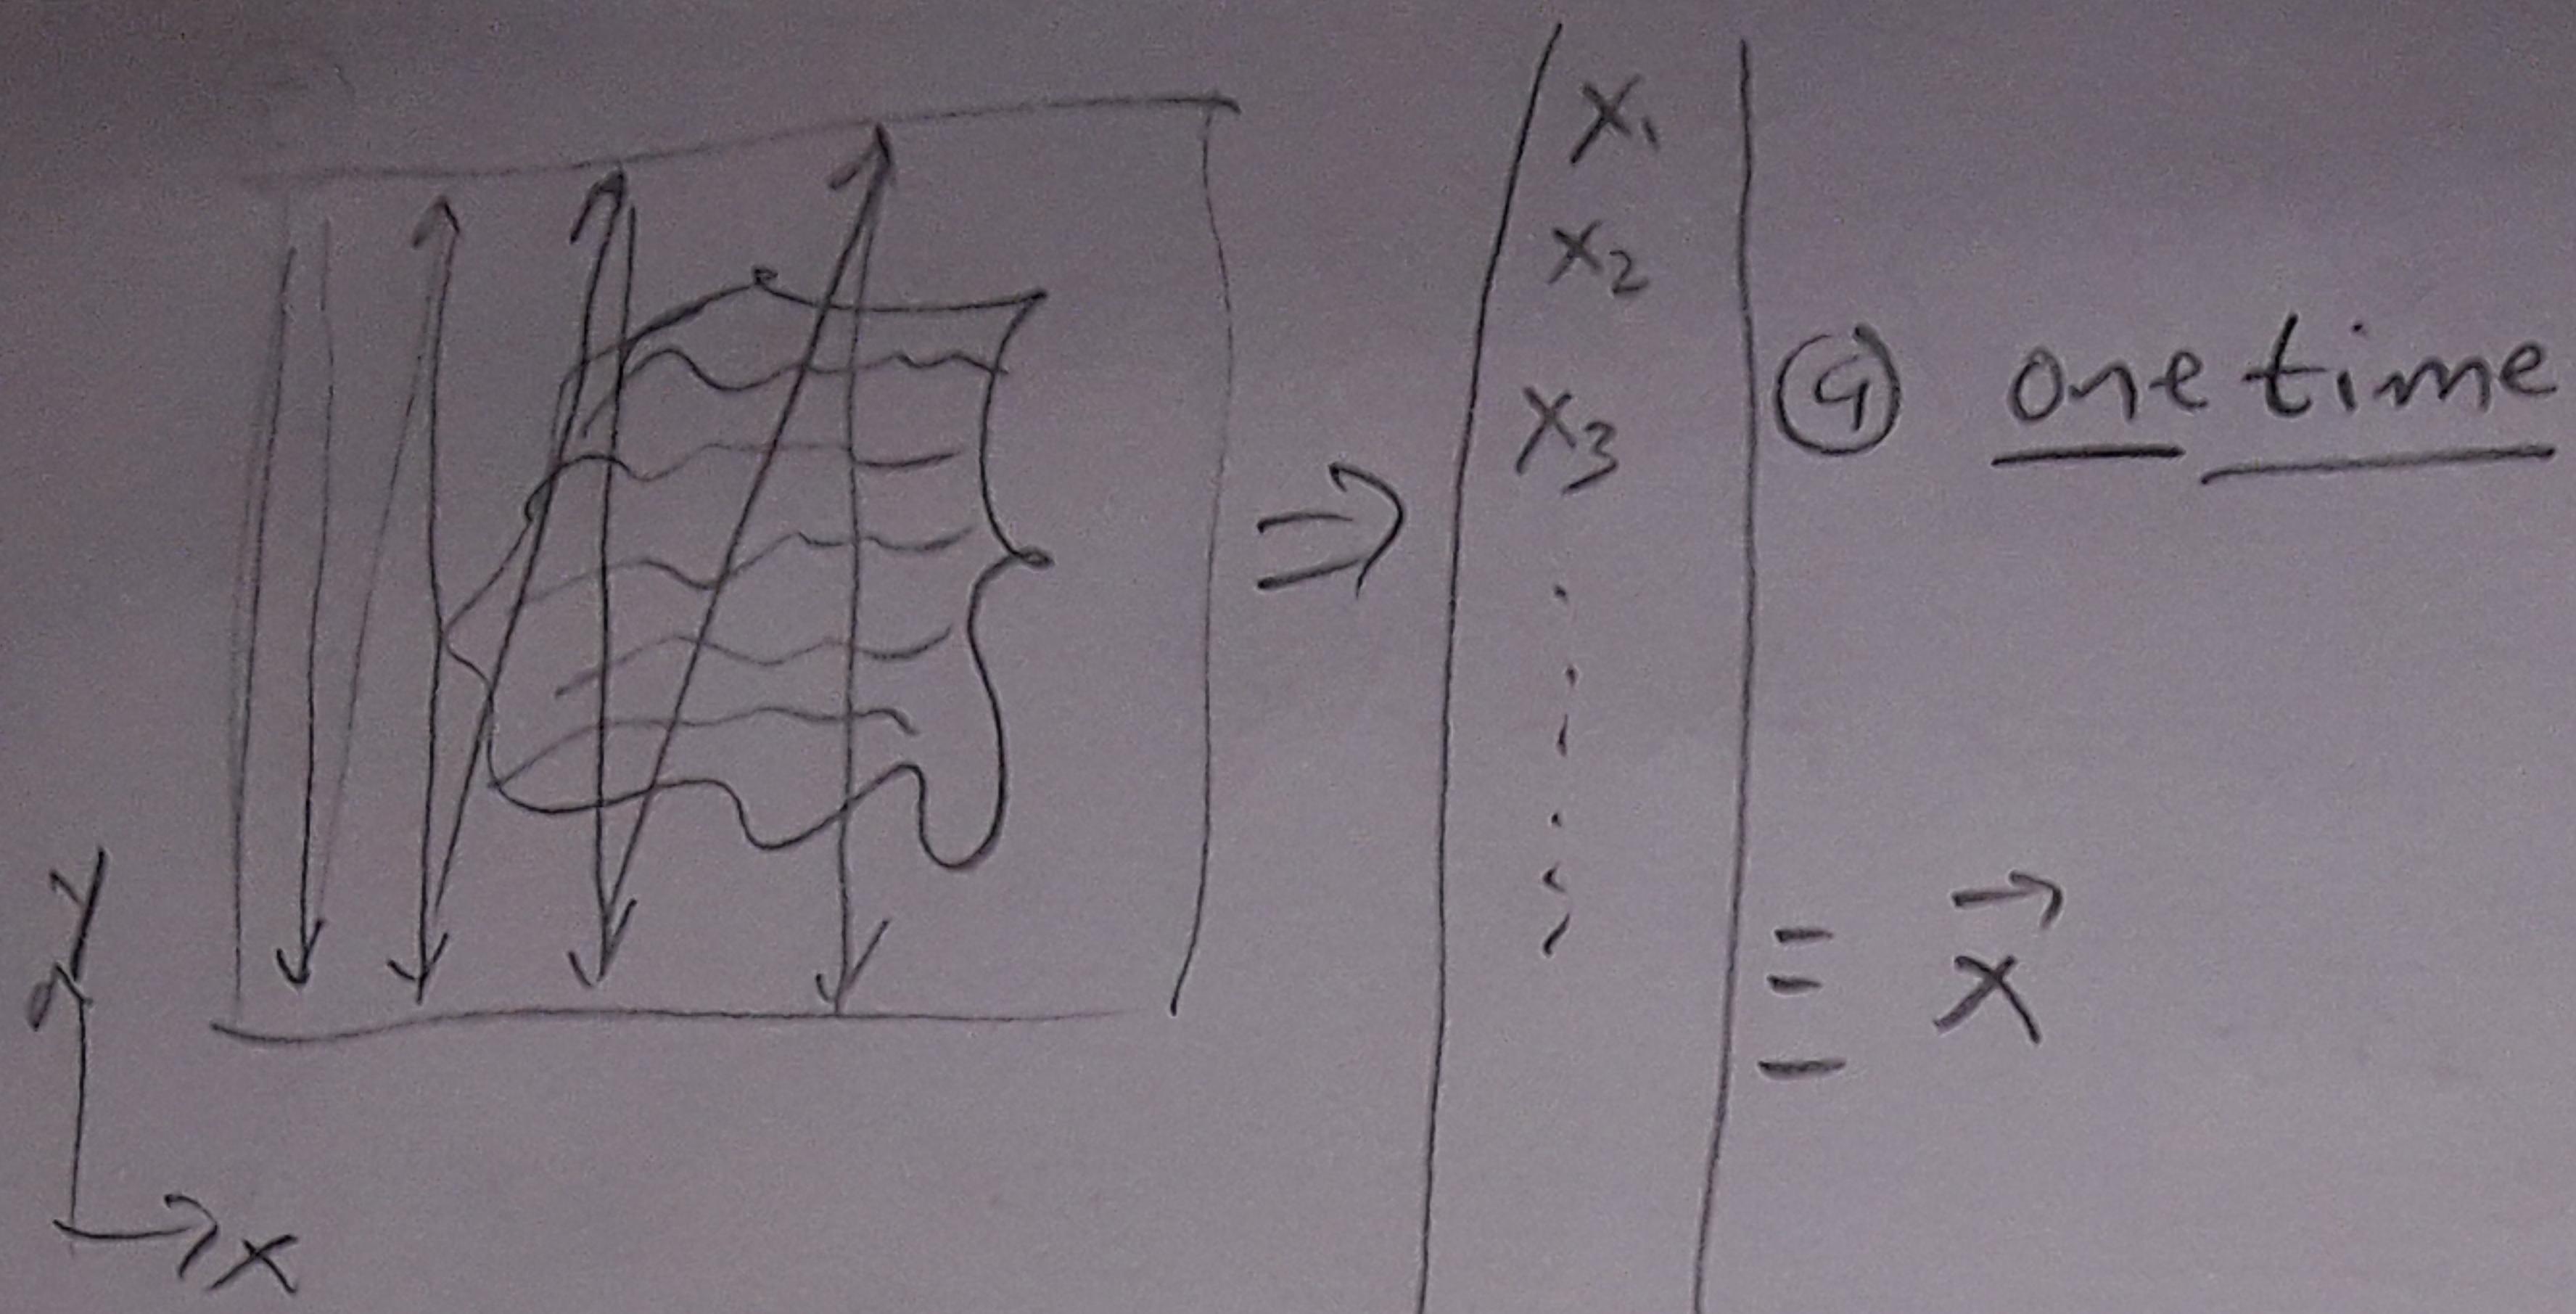

$\underline{X}$  and  $\underline{X}'$  are matrices which represent time-series of data whose column vectors' are data at a single time step. Each subsequent column are the next time steps.  $\underline{X}$  are time steps  $1 \dots N_{t-1}$  and  $\underline{X}'$  are the time steps advanced by one,  $2 \dots N_t$

$\underline{\Phi}$  are DMD modes found

To "replay" the data as an animation, project the first animation frame onto  $\underline{\Phi}$ .

$$\overset{\rightarrow}{X}(t=1) = \underline{\Phi} \vec{c} \quad \text{so} \quad \vec{c} = \underline{\Phi}^{-1} \overset{\rightarrow}{X}_1$$

then  $\underline{X}(t) = [e^{\underline{\Phi}t}] \vec{c} \Rightarrow$  provides a new animation in continuous time with the ability to predict times past the end of the data = prediction!

①

$$\underline{X} = \left( \vec{x}(t_1) \vec{x}(t_2) \vec{x}(t_3) \dots \vec{x}(t_{N_t}) \right) \quad \Rightarrow \text{animation of time frames}$$

$N_p \times (N_t - 1)$

$$N_t \ll N_p \quad (\sim 10^3) \quad (\sim 10^5 - 10^7)$$

$$\underline{X}' = \underline{AX}$$

$\underline{X}' = N_p \times (N_t - 1) \quad \text{for time frames } t = 2 \dots N_t$   
 $= \text{one time frame in the future}$

↑  $A$  acts as a time-evolution operator  
where  $\hat{A} \equiv \text{Koopman Operator}$   $\hat{A} = \frac{N_p \times N_p}{\text{large!}}$

$$\stackrel{\text{so}}{=} \underline{A} = \underline{X}' \underline{X}^{-1}$$

using SVD of  $\underline{X}$

$$\underline{X} = \underline{U} \underline{\Sigma} \underline{V}^+$$

where  $\underline{U} \equiv$  orthogonal matrix  
 $N_p \times N_p$

$\underline{\Sigma} \equiv$  Diagonal matrix  
 $N_p \times N_{t-1}$

$\underline{V} \equiv$  orthogonal matrix  
 $N_{t-1} \times N_{t-1}$

and  $\underline{X} \underline{X}^+ \underline{U} = \underline{U} \underline{\Sigma}^2$

$\underline{U}$  are eigenvectors of  $\underline{X} \underline{X}^+$

$$\underline{X}^+ \underline{X} \underline{V} = \underline{V} \underline{\Sigma}^2$$

$\underline{V}$  " " "  $\underline{X}^+ \underline{X}$

$$\underline{A} = \underline{X}' \underline{V} \underline{\Sigma}^{-1} \underline{U}^+ \quad \left. \begin{array}{l} \underline{U} = N_p \times N_p \quad \underline{\Sigma} = N_p \times N_{t-1} \\ \text{in economy mode} \end{array} \right\}$$

$$\underline{A} \underline{U} = \underline{X}' \underline{V} \underline{\Sigma}^{-1} \quad \left. \begin{array}{l} \underline{U} = N_p \times N_{t-1} \quad \underline{\Sigma} = N_{t-1} \times N_{t-1} \\ \text{in econ mode} \end{array} \right\}$$

$N_p \times N_{t-1}$   $\Rightarrow$  so solve the eigenmode problem in  
 in econ mode the lower dimensional space

Define  $\tilde{A} = \underline{U}^+ \underline{A} \underline{U}$  solve eigenvcs  $\tilde{A} \tilde{w} = \tilde{w} \Lambda$

$(N_{t-1} \times N_{t-1})$

where  $\tilde{A} = \underline{X}' \underline{V} \underline{\Sigma}^{-1} \underline{U}$

$\tilde{A} \tilde{w} = \underline{U}^+ \underline{X}' \underline{V} \underline{\Sigma}^{-1} \tilde{w} = \underline{U}^+ \tilde{A} \tilde{w} \Rightarrow \underline{U} \tilde{A} \tilde{w} = \underline{U} \underline{U}^+ \tilde{A} \tilde{w} = \tilde{A} \tilde{w}$

$$\underline{U} \tilde{A} \underline{W} = \cancel{\underline{U} \underline{U}^T} \underline{A} \underline{W} = \underline{A} \underline{W} = \underline{\underline{\Phi}} \quad \textcircled{3}$$

we want to show  $\underline{A} \underline{\underline{\Phi}} = \underline{\underline{\Phi}} \underline{\Lambda}$

$$\underline{\Lambda} = \underline{W}^T \tilde{A} \underline{W}$$

$$\underline{A} \underline{W} \underline{\Lambda} = \underline{\underline{\Phi}} \underline{\Lambda}$$

$$\underline{A} \underline{W} \cancel{\underline{W}^T \tilde{A} \underline{W}} = \underline{\underline{\Phi}} \underline{\Lambda}$$

$$\underline{A} \underline{W} \tilde{A} \underline{W} = \underline{\underline{\Phi}} \underline{\Lambda}$$

$$\underline{A} \underline{\underline{\Phi}} = \underline{\underline{\Phi}} \underline{\Lambda} \quad \checkmark$$

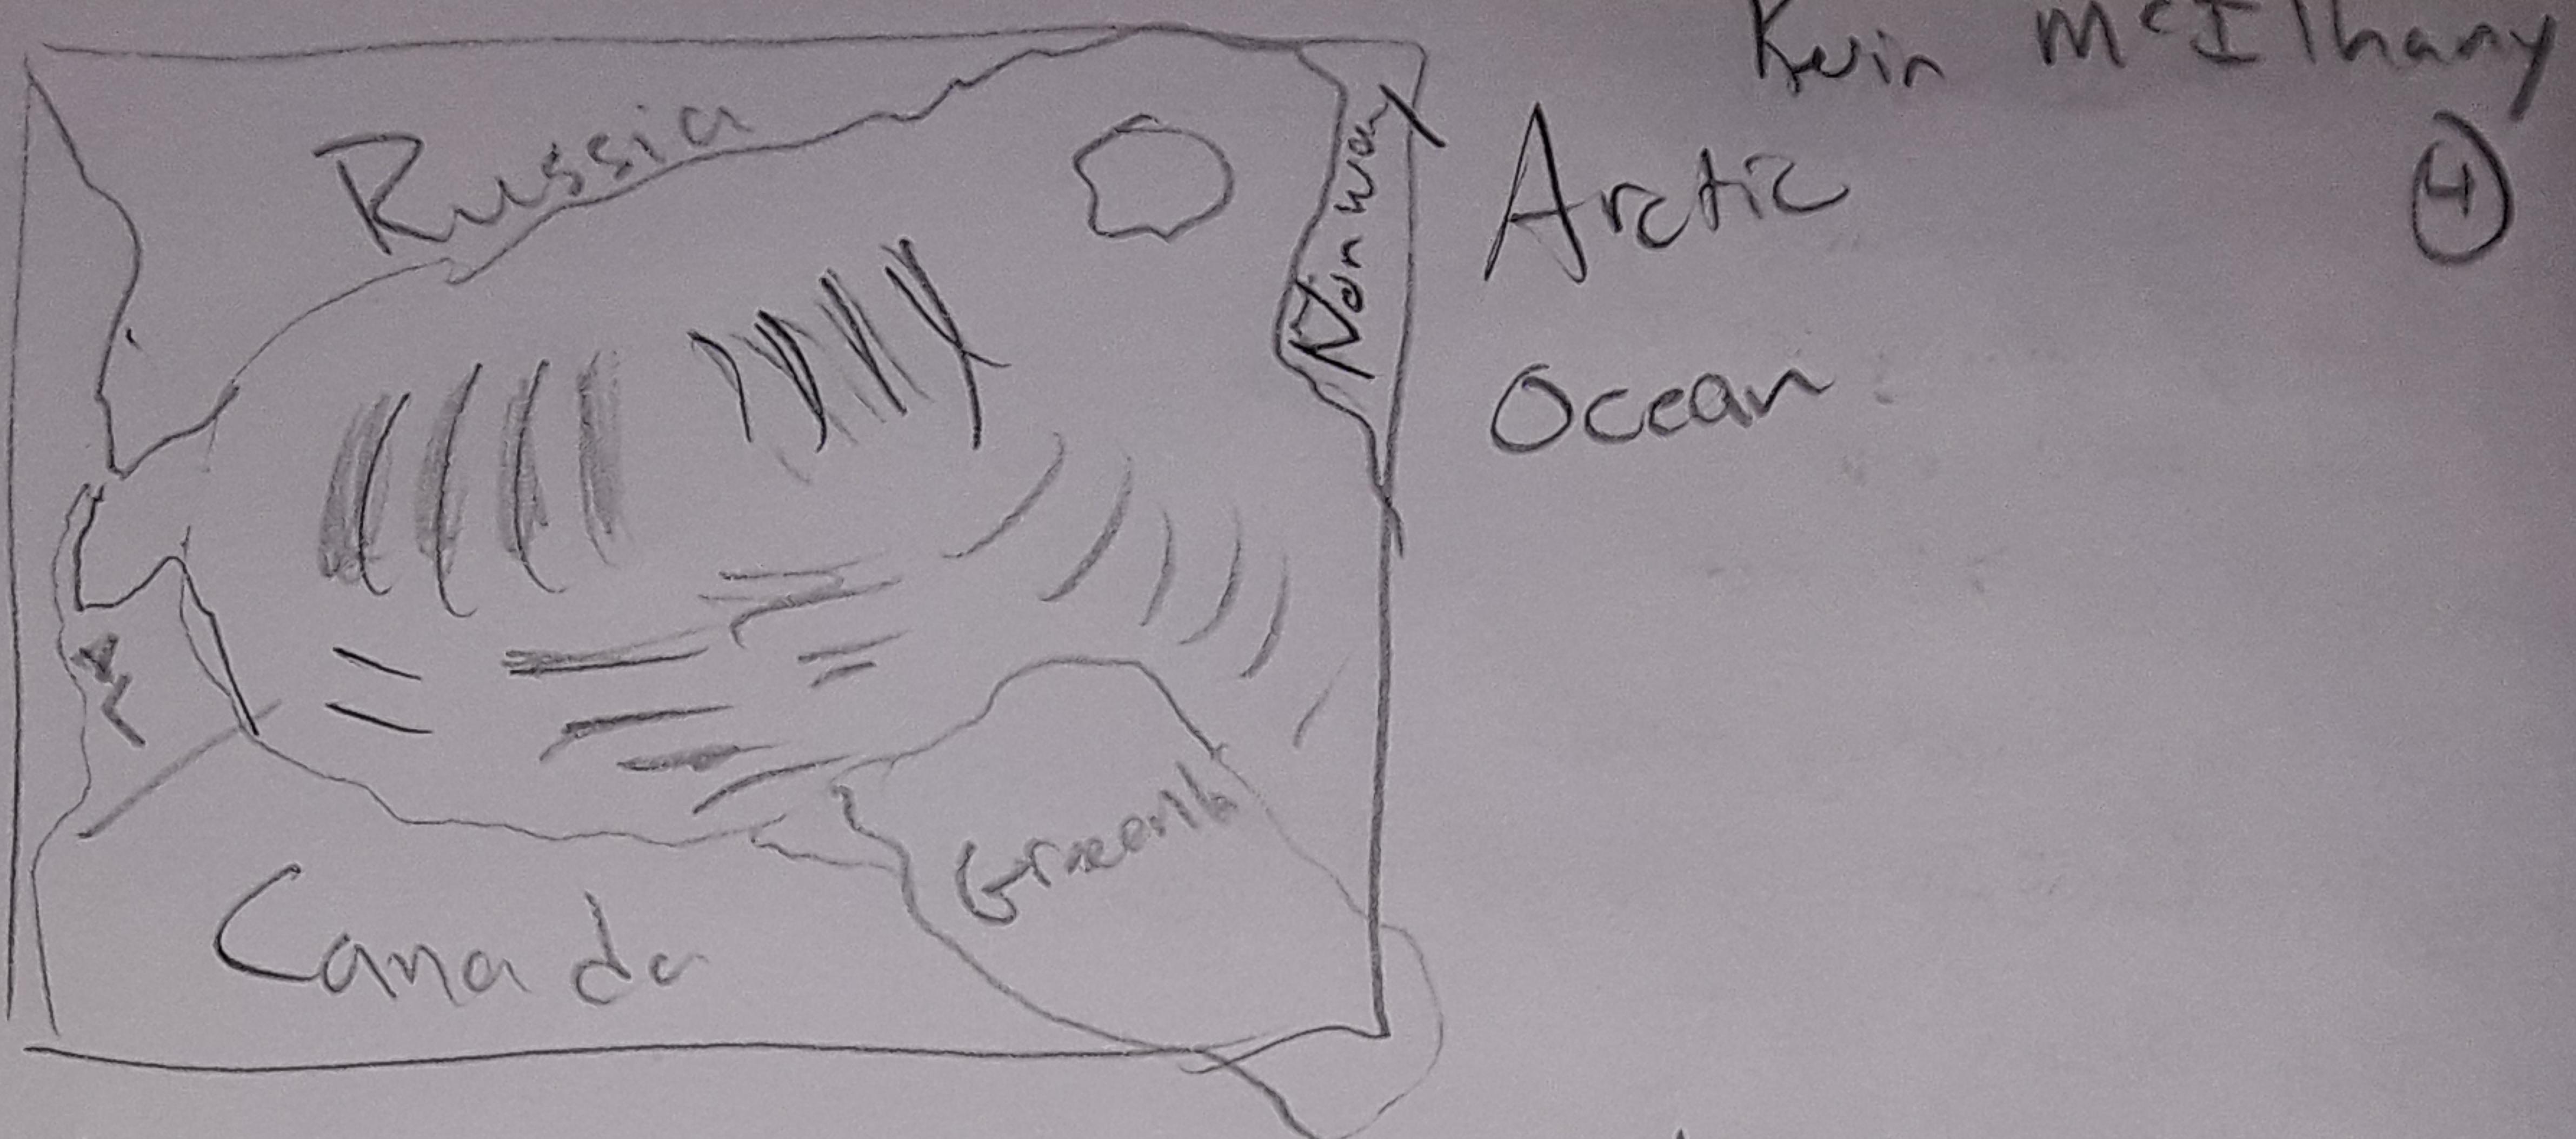

$$\tilde{A} = N_{t-1} \times N_{t-1}$$

$$\underline{W} = N_{t-1} \times N_{t-1}$$

$$\underline{\Lambda} = N_{t-1} \times N_{t-1} = \text{eigenvalues}$$

$$\underline{\underline{\Phi}} = N_p \times N_{t-1} = \text{DMD modes}$$

$\Phi_1(x,y)$

DMD modes appear to have spatial structure but, in truth,  $\Phi$  are modes whose information per location is the local  $\lambda$ -values  $\in$  time-like info.

What happens if Russia blockades part of the arctic? This is called a data-denied region?

\* Use neural networks trained based on previously computed DMD,  $\Phi$   
NN can provide data within the denied-zone via interpolation  $\Rightarrow$  recover your prediction capability,
